Frese SIGMA Compact
- dynamic balancing valve

Description

The Frese SIGMA Compact is an externally adjustable dynamic balancing valve that provides simple, accurate and reliable flow limitation and isolation in heating and cooling systems.

Application

The Frese SIGMA Compact can be used in both heating and cooling systems for the effective distribution of flow in various sections of the system.

The Frese SIGMA Compact can be used instead of traditional double regulating valves and can be installed in both variable flow systems and constant flow systems.

Operation

The Frese SIGMA Compact can be set to the required position easily by using the hand wheel to limit the flow rate in certain parts of a system, eradicating overflows and the unnecessary wastage of energy. The internal differential pressure control function of the Frese SIGMA Compact ensures that the set flow rate is limited irrespective of pressure fluctuations in the system.

Once the valve has been pre-set to the desired flow rate, the hand wheel can be set in position. From this position, the valve can be fully closed for isolation purposes and easily re-opened back to the required set point.

Features

• Easy adjustment of the flow using the hand wheel

• Isolation function up to 10 bar differential pressure

• Maximum flow position can be set for easy reopening to pre-set flow position, after the valve has been used for isolation

• Clear setting scale located on the hand wheel

• No minimum straight pipe lengths required before or after the valve

• Built-in P/T plugs for needle system

Benefits

• Easy to size and select as only the flow rate is required

• Simplified system design with the number of balancing valves being reduced

• Works as a flow limiter ensuring no overflows

• Easy to install and adjust on site

• Provides flexibility if the system is modified after the initial installation

• Simplifies the commissioning process and reduces commissioning time due to automatic balancing of the system

• High level comfort for the end-users as a result of the correct balance of the hydraulic system

• Reliable operation as a dynamic balancing valve automatically finds the hydraulic balance regardless of pressure fluctuations in the system

• Reduces the number of valves to install as no main circuit or branch balancing valves needed in the system

• No need for straight pipe before and after the valve

Frese SIGMA Compact
- dynamic balancing valve

Function

The Frese SIGMA Compact reacts to pressure fluctuations in a system in order to keep the differential pressure across the pre-set unit constant. By achieving this, a maximum flow limit is ensured in accordance with the design.
The following applies to all flow control valves:

$$Q = kV * \sqrt{\Delta p}$$

Q = Flow (m³/h)
kV = Opening area
Δp = Differential pressure (Bar)

Flow Characteristic

The illustration shows how the flow in a Frese SIGMA Compact valve reacts in accordance to the pump pressure. For comparison we have added a typical flow characteristic for a static balancing valve.

The differential pressure function of the valve will work when the differential pressure provided by the pump is sufficient to meet the required minimum differential pressure (which is dependent upon the required flow rate).

Once the minimum differential pressure is satisfied, the set flow rate is maintained regardless of any pressure fluctuations in the system.

Q Flow

Setting the Valve

The Frese SIGMA Compact is easily set using the pre-setting scale located on the hand wheel.

The set point of the valve can be determined by using the flow graphs or tables (page 7 to 14) or the Frese APP for the valve dimension in question.

The scale on the hand wheel is for the adjustment of flow. To use the valve for isolation, turn the handle clockwise to the fully closed position.

Pre-setting max flow position.
- Set the valve handle to the desired flow
- Remove cap marked Frese, and tighten (turn clockwise) with 2mm hexagonal key
- The valve can then be reopened to the pre-set flow after the valve has been used for isolation

To set the valve to another flow position, loosen the valve pre-setting with the 2mm hexagonal key (turn anti clockwise) and set the valve handle to the new flow position and tighten.

Turn the hand wheel clockwise for isolation

Turn clockwise with 2mm hexagonal key to set the valve to max flow position

Frese SIGMA Compact
- dynamic balancing valve

Verification of Dynamic Systems

In general the flow rate in a system can be verified in two ways:
- Direct flow rate verification in a circuit
- Measurement of the differential pressure across the balancing valve or metering station

Direct flow rate verification
This can for example, be carried out by ultrasonic equipment. On the basis of the measured velocity of the flow and the pipe dimension the software will compute a flow rate. The use of ultrasonic verification requires free access to the pipes as the sensors are fitted directly to the pipe.

Measurement of the differential pressure
This is the main method of flow verification.

Once the design flow rate is known, the valve can be set using the flow graphs or Frese APP. Either of these tools will show the required set point and the required minimum differential pressure for the set flow rate.

Once the differential pressure has been verified, the flow rate can be recorded according to the flow rate graphs provided.

If the measured differential pressure is below the minimum Δp required for that set point, the flow can be found by using the formulas below.

Flow Calculation

$Q = kV \cdot \sqrt{\Delta p}$	$Q = m^3/h$ $\Delta p = Bar$
$Q = kV \cdot 100 \cdot \sqrt{\Delta p}$	$Q = l/h$ $\Delta p = kPa$
$Q = \dfrac{kV}{36} \cdot \sqrt{\Delta p}$	$Q = l/s$ $\Delta p = kPa$

Measurement of the differential pressure (Δp) across the valve

Frese SIGMA Compact
- dynamic balancing valve

Application Diagrams

Frese SIGMA Compact installed in a circuit with heating or cooling coils

The system is easily balanced by adjusting the pump according to the required differential pressure across the valve located at the furthest point from the pump, known as the critical valve (P+ - P-).
When the minimum required differential pressure is available at the critical valve, sufficient differential pressure will be available in the rest of the system and the system will be automatically balanced.

Frese SIGMA Compact in installations with injection circuits

Please note:
The balance is controlled by the Frese SIGMA Compact valves fitted in each control zone.
Major branch balancing valves are eliminated, even if the system may be larger and with far more branches than shown in this diagram.

Flow rate example Frese SIGMA Compact DN15 High
Required design flow rate 600 l/h - 0,167 l/s
1. The required design flow rate is used as the point of reference for the overall rating of dynamic systems. (See the graph)

2. The pre-setting for the valve can be determined using the flow rate graph or the Frese APP.
Setting = 2.2

3. On the right axis, the minimum differential pressure required from the pump can be determined.
Minimum DP required approx. 14.5 kPa.

Technical Data

|	
Housing DN15-32:	DZR Brass CW602N
DN40-50:	Ductile Iron GJS-400
Flow setting:	PA6 (20% glass)
Spring:	Stainless steel
Diaphragm:	HNBR
O-rings:	EPDM
Pressure class:	PN25
Max. differential pressure:	400 kPa
Temperature range:	-10^0C to $+120^0$C

The pipe system shall be properly ventilated to avoid risk of air pockets. Glycolic mixtures up to 50% are applicable (both ethylene and propylene).
Recommendation: Water treatment to VDI 2035.

Text for Technical Specifications

- The valve should be a dynamic balancing valve with the option of setting the flow without interference of operation.
- The valve should include P/T plugs for the verification of differential pressure.
- The valve should only be adjustable by means of a hand wheel to limit the maximum flow.
- The flow setting control unit shall be pressure independent.
- The dynamic balancing valve shall contain a combined flow setting and differential pressure control bonnet assembly.
- The valve housing shall be DZR brass for DN15-32 and ductile iron for DN40-50.
- The valve shall have a spring made of stainless steel, a diaphragm made of HNBR and O-rings made of EPDM.
- The valve housing shall be PN25 rated and suitable for 120℃.
- The valve shall have a thread according to ISO 228.
- The valve shall have a maximum operating differential pressure of 400 kPa (4 Bar)
- The valve shall have an external adjustable analogue stepless pre-setting scale from minimum to maximum flow.
- The valve in isolated position shall have a leakage rate at maximum 0.01% of maximum rated volumetric flow and comply to EN1349 Class IV with a maximum differential pressure of 10 Bar.
